“Obesity Treatment in Preschool Age Children”

Though 2 million children ages 2 to 5 years meet criteria for obesity, there are few clinical trials of treatments to reduce obesity in this age group. Eating and activity behaviors are formed in the preschool years, thus, interventions to increase healthy eating and physical activity have the potential to change the immediate and longer-term trajectory of obesity. This talk will describe the results of a randomized clinical trial of behavioral intervention to change preschool children’s body mass index.
